PREAMBLE

Keeping pace with the stream of new data and evolving evidence on which guideline recommendations are based is an ongoing challenge to timely development of clinical practice guidelines. In an effort to respond promptly to new evidence, the American College of Cardiology Foundation/American Heart Association (ACCF/AHA) Task Force on Practice Guidelines (Task Force) has created a “focused update” process to revise the existing guideline recommendations that are affected by the evolving data or opinion. New evidence is reviewed in an ongoing fashion to more efficiently respond to important scientific and treatment trends that could have a major impact on patient outcomes and quality of care. Evidence is reviewed at least twice a year, and updates are initiated on an as-needed basis and completed as quickly as possible while maintaining the rigorous methodology that the ACCF and AHA have developed during their partnership of >20 years.

These updated guideline recommendations reflect a consensus of expert opinion after a thorough review primarily of late-breaking clinical trials identified through a broad-based vetting process as being important to the relevant patient population, as well as other new data deemed to have an impact on patient care (see Section 1.1, Methodology and Evidence Review, for details). This focused update is not intended to represent an update based on a complete literature review from the date of the previous guideline publication. Specific criteria/considerations for inclusion of new data include the following:

- publication in a peer-reviewed journal;
- large, randomized, placebo-controlled trial(s);
- nonrandomized data deemed important on the basis of results affecting current safety and efficacy assumptions, including observational studies and meta-analyses;

This document was approved by the American College of Cardiology Foundation Board of Trustees and the American Heart Association Science Advisory and Coordinating Committee in July 2011.

• strength/weakness of research methodology and findings;
• likelihood of additional studies influencing current findings;
• impact on current and/or likelihood of need to develop new performance measure(s);
• request(s) and requirement(s) for review and update from the practice community, key stakeholders, and other sources free of relationships with industry or other potential bias;
• number of previous trials showing consistent results; and
• need for consistency with a new guideline or guideline updates or revisions.

Selected members of the previous writing committee as well as other experts in the subject under consideration are chosen by the ACCF and AHA to examine subject-specific data and to write guidelines in partnership with representatives from other medical organizations and specialty groups. Writing group members review the selected late-breaking clinical trials and other new data that have been vetted through the Task Force; weigh the strength of evidence for or against particular tests, treatments, or procedures; and include estimates of expected outcomes where such data exist. Patient-specific modifiers, comorbidities, and issues of patient preference that may influence the choice of tests or therapies are considered. When available, information from studies on cost is considered, but data on efficacy and outcomes constitute the primary basis for the recommendations contained herein.

In analyzing the data and developing recommendations and supporting text, the writing group uses evidence-based methodologies developed by the Task Force. The Class of Recommendation (COR) is an estimate of the size of the treatment effect considering risks versus benefits in addition to evidence and/or agreement that a given treatment or procedure is or is not useful/effective or in some situations may cause harm. The Level of Evidence (LOE) is an estimate of the certainty or precision of the treatment effect. The writing group reviews and ranks evidence supporting each recommendation with the weight of evidence ranked as LOE A, B, or C according to specific definitions that are included in Table 1. Studies are identified as observational, retrospective, prospective, or randomized where appropriate. For certain conditions for which inadequate data are available, recommendations are based on expert consensus and clinical experience and are ranked as LOE C. When recommendations at LOE C are supported by historical clinical data, appropriate references (including clinical reviews) are cited if available. For issues for which sparse data are available, a survey of current practice among the clinicians on the writing group is the basis for LOE C recommendations, and no references are cited. The schema for COR and LOE is summarized in Table 1, which also provides suggested phrases for writing recommendations within each COR. A new addition to this methodology is a separation of the Class III recommendations to delineate whether the recommendation is determined to be of “no benefit” or is associated with “harm” to the patient. In addition, in view of the increasing number of comparative effectiveness studies, comparator verbs and suggested phrases for writing recommendations for the comparative effectiveness of one treatment or strategy versus another have been added for COR I and IIa, LOE A or B only.

In view of the advances in medical therapy across the spectrum of cardiovascular diseases, the Task Force has designated the term guideline-directed medical therapy (GDMT) to represent optimal medical therapy as defined by ACCF/AHA guideline-recommended therapies (primarily Class I). This new term, GDMT, will be used herein and throughout all future guidelines.

Because the ACCF/AHA practice guidelines address patient populations (and healthcare providers) residing in North America, drugs that are not currently available in North America are discussed in the text without a specific COR. For studies performed in large numbers of subjects outside North America, each writing group reviews the potential influence of different practice patterns and patient populations on the treatment effect and relevance to the ACCF/AHA target population to determine whether the findings should inform a specific recommendation.

The ACCF/AHA practice guidelines are intended to assist healthcare providers in clinical decision making by describing a range of generally acceptable approaches to the diagnosis, management, and prevention of specific diseases or conditions. The guidelines attempt to define practices that meet the needs of most patients in most circumstances. The ultimate judgment regarding care of a particular patient must be made by the healthcare provider and patient in light of all the circumstances presented by that patient. As a result, situations may arise for which deviations from these guidelines may be appropriate. Clinical decision making should involve consideration of the quality and availability of expertise in the area where care is provided. When these guidelines are used as the basis for regulatory or payer decisions, the goal should be improvement in quality of care. The Task Force
A recommendation with Level of Evidence B or C does not imply that the recommendation is weak. Many important clinical questions addressed in the guidelines do not lend themselves to clinical trials. Although randomized trials are unavailable, there may be a very clear clinical consensus that a particular test or therapy is useful or effective.

*Data available from clinical trials or registries about the usefulness/efficacy in different subpopulations, such as sex, age, history of diabetes, history of prior myocardial infarction, history of heart failure, and prior aspirin use.

†For comparative effectiveness recommendations (Class I and IIa; Level of Evidence A and B only), studies that support the use of comparator verbs should involve direct comparisons of the treatments or strategies being evaluated.

recognizes that situations arise in which additional data are needed to inform patient care more effectively; these areas will be identified within each respective guideline when appropriate.

Prescribed courses of treatment in accordance with these recommendations are effective only if followed. Because lack of patient understanding and adherence may adversely affect outcomes, physicians and other healthcare providers should make every effort to engage the patient’s active participation in prescribed medical regimens and lifestyles. In addition, patients should be informed of the risks, benefits, and alternatives to a particular treatment and be involved in shared decision making whenever feasible, particularly
for COR IIa and IIb, for which the benefit-to-risk ratio may be lower.

The Task Force makes every effort to avoid actual, potential, or perceived conflicts of interest that may arise as a result of industry relationships or personal interests among the members of the writing group. All writing group members and peer reviewers of the guideline are asked to disclose all such current relationships as well as those existing 12 months previously. In December 2009, the ACCF and AHA implemented a new policy for relationships with industry and other entities (RWI) that requires the writing group chair plus a minimum of 50% of the writing group to have no relevant RWI (Appendix 1 for the ACCF/AHA definition of relevance). These statements are reviewed by the Task Force and all members during each conference call and/or meeting of the writing group and are updated as changes occur. All guideline recommendations require a confidential vote by the writing group and must be approved by a consensus of the voting members. Members are not permitted to write, and must recuse themselves from voting on, any recommendation or section to which their RWI apply. Members who recused themselves from voting are indicated in the list of writing group members, and section recusals are noted in Appendix 1. Authors’ and peer reviewers’ RWI pertinent to this guideline are disclosed in Appendices 1 and 2, respectively. Additionally, to ensure complete transparency, writing group members’ comprehensive disclosure information—including RWI not pertinent to this document—is available as an online supplement. Comprehensive disclosure information for the Task Force is also available online at www.cardiosource.org/Acc/About-Acc/Leadership/Guidelines-and-Documents-Task-Forces.aspx. The work of the writing group was supported exclusively by the ACCF and AHA without commercial support. Writing group members volunteered their time for this activity.

In an effort to maintain relevance at the point of care for practicing physicians, the Task Force continues to oversee an ongoing process improvement initiative. As a result, in response to pilot projects, several changes to these guidelines will be apparent, including limited narrative text and a focus on summary and evidence tables.

The recommendations in this focused update will be considered current until they are superseded by another focused update or the full-text guideline is revised. Guidelines are official policy of both the ACCF and AHA.

Alice K. Jacobs, MD, FACC, FAHA Chair
ACCF/AHA Task Force on Practice Guidelines

1. INTRODUCTION

1.1. Methodology and Evidence Review

The results of late-breaking clinical trials presented at the annual scientific meetings of the ACC, AHA, European Society of Cardiology, Society for Vascular Surgery, Society of Interventional Radiology, and Society for Vascular Medicine, as well as selected other data/articles published through December 2010, were reviewed by the 2005 guideline writing committee along with the Task Force and other experts to identify those trials and other key data that may impact guideline recommendations. On the basis of the criteria/considerations noted above, recent trial data and other clinical information were considered important enough to prompt a focused update of the “ACCF/AHA 2005 Guidelines for the Management of Patients With Peripheral Arterial Disease (Lower Extremity, Renal, Mesenteric, and Abdominal Aorta)”2 Because clinical research and clinical care of vascular disease have a global investigative and international clinical care tradition, efforts were made to harmonize this update with the Trans-Atlantic Inter-Society Consensus document on Management of Peripheral Arterial Disease (TASC) and the Inter-Society Consensus for the Management of Peripheral Arterial Disease (TASC II) Steering Committee guideline writing efforts.3

To provide clinicians with a comprehensive set of data, whenever deemed appropriate or when published, the absolute risk difference and number needed to treat or harm are provided in the guideline, along with confidence intervals (CIs) and data related to the relative treatment effects, such as odds ratio, relative risk, hazard ratio (HR), or incidence rate ratio.

Consult the full-text version2 or executive summary4 of the “ACCF/AHA 2005 Guidelines for the Management of Patients With Peripheral Arterial Disease (Lower Extremity, Renal, Mesenteric, and Abdominal Aorta)” for policy on clinical areas not covered by the focused update. Individual recommendations modified in this focused update will be incorporated into future revisions and/or updates of the full-text guideline.

1.2. Organization of the Writing Group

For this focused update, all eligible members of the 2005 writing committee were invited to participate; those who agreed (referred to as the 2011 focused update writing group) were required to disclose all RWI relevant to the data under consideration. In addition, new members were invited in order to preserve the required RWI balance. The writing group included representatives from the ACCF, AHA, Society for Catheterization and Cardiovascular Interventions DOI 10.1002/ccd. Published on behalf of The Society for Cardiovascular Angiography and Interventions (SCAI).

1.3. Document Review and Approval

This document was reviewed by 2 official reviewers each nominated by the ACCF and the AHA, as well as 2 reviewers each from the Society for Cardiovascular Angiography and Interventions, Society of Interventional Radiology, Society for Vascular Medicine, and Society for Vascular Surgery; and 13 individual content reviewers (including members from the following groups: ACCF/AHA Task Force on Clinical Data Standards, ACCF Interventional Scientific Council, 2005 Peripheral Artery Disease Writing Committee, ACCF/AHA Task Force on Performance Measures, ACCF Prevention Committee, and ACCF Peripheral Vascular Disease Committee). All information on reviewers’ RWI was distributed to the writing group and is published in this document (Appendix 2).

This document was approved for publication by the governing bodies of the ACCF and AHA and endorsed by the Society for Cardiovascular Angiography and Interventions, Society of Interventional Radiology, Society for Vascular Medicine, and Society for Vascular Surgery.

1.4. Scope of the Focused Update

Studies relevant to the management of patients with peripheral artery disease (PAD) (lower extremity, renal, mesenteric, and abdominal aortic) were identified and reviewed as described previously in Section 1.1. On the basis of these data, the writing group determined that updates to the 2005 recommendations were necessary for lower extremity and abdominal aortic disease but that the existing recommendations for renal and mesenteric disease remain valid.4 Although the specific recommendations for renal and mesenteric disease did not change, the following observations and clarifications were made:

1. Medical therapy for renal disease: No new pivotal trials or studies were identified.
2. Revascularization for renal disease: The writing group acknowledges that some new studies support a more limited role for renal revascularization. For example, the ASTRAL (Angioplasty and Stent for Renal Artery Lesions) investigators5 concluded that there were substantial risks but no clinical benefit from revascularization in patients with atherosclerotic renovascular disease. The writing group concurred that the criteria for patient selection in this randomized controlled trial (RCT) potentially excluded many patients who might have benefitted from intervention. It is anticipated that ongoing studies such as the CORAL (Cardiovascular Outcomes in Renal Atherosclerotic Lesions) trial6 will provide additional evidence relevant to these recommendations in the near future.

The 2011 focused update acknowledges the declining use of surgical revascularization and the increasing use of catheter-based revascularization for renal artery stenoses. The writing group determined that new data support the equivalency of surgical and endovascular treatment, with lower morbidity and mortality associated with endovascular treatment but higher patency rates with surgical treatment in those patients who survived for at least 2 years after randomization.5 The writing group also notes that new data suggest that 1) the efficacy of revascularization may be reduced in patients with branch artery stenoses7 and 2) patients undergoing renal artery bypass may do best when surgery is performed in high-volume centers.8

2. LOWER EXTREMITY PAD

2.5. Diagnostic Methods

2.5.1. Recommendations for Ankle-Brachial Index, Toe-Brachial Index, and Segmental Pressure Examination. Table 2 contains recommendations for ankle-brachial index (ABI), toe-brachial index, and segmental pressure examination. See Appendix 3 for supplemental information.

The German Epidemiologic Trial on Ankle Brachial Index Study Group included 6880 patients ≥65 years of age and demonstrated that 21% of the cohort had either asymptomatic or symptomatic PAD.11 On the basis of this large epidemiologic study, the 2011 writing group modified the age for consideration of ABI diagnostic testing to ≥65 years. The writing group considered the potential impact of lowering the PAD detection age to 65 years, acknowledging that the ABI test would be used in an incrementally larger “at-risk” population. This reflects the intent of both the original evidence-based document and this focused update to blunt the profound ongoing underdiagnosis and undertreatment of individuals with PAD until limb ischemic symptoms have become severe. This ABI recommendation is intended for office-based and vascular laboratory diagnostic use and is not intended to serve as a population screening tool. The writing group noted with confidence that no other cardiovascular disease diagnostic test can be applied in an age-defined clinical population.

</tr>
<tr>
<td>2. ABI results should be uniformly reported with noncompressible values defined as greater than 1.40, normal values 1.00 to 1.40, borderline 0.91 to 0.99, and abnormal 0.90 or less.24 (Level of Evidence: B)</td>
<td>New recommendation</td>
<td></td>
</tr>
</tbody>
</table>

ABI indicates ankle-brachial index; and PAD, peripheral artery disease.

population with such a high detection rate, low to no risk, and low cost. We encourage expansion of the evidence base by design and completion of ABI screening studies.

The definitions of normal and abnormal ABI values have been modified based on publication of the results of the Ankle Brachial Index Collaboration.24 This includes a normal ABI range of 1.00 to 1.40, and abnormal values continue to be defined as those ≤0.90. ABI values of 0.91 to 0.99 are considered “borderline” and values >1.40 indicate noncompressible arteries.

The 2005 recommendations stated that segmental pressure measurements are useful in the diagnosis and anatomic localization of lower extremity PAD. The 2011 writing group recognized that vascular diagnostic laboratories could use segmental pressures, Doppler waveform analysis, pulse volume recordings, or ABI with duplex ultrasonography (or some combination of these methods) to document the presence and location of PAD in the lower extremity.

2.6. Treatment

2.6.1.4. Recommendations for Smoking Cessation. Table 3 contains recommendations for smoking cessation. See Appendix 3 for supplemental information.

No prospective RCTs have examined the effects of smoking cessation on cardiovascular events in patients with lower extremity PAD. Observational studies have found that the risk of death, myocardial infarction, and amputation is substantially greater, and lower extremity angioplasty and open surgical revascularization patency rates are lower in individuals with PAD who continue to smoke than in those who stop smoking.34–36 In some studies, exercise time is greater in patients who stop smoking than in current smokers.37,38 Efforts to achieve smoking cessation are recommended for patients with lower extremity PAD. Physician advice coupled with frequent follow-up achieves 1-year smoking cessation rates of approximately 5% compared with only 0.1% in individuals who try to quit smoking without a physician’s intervention.39 With pharmacological
interventions such as nicotine replacement therapy and bupropion, 1-year smoking cessation rates of approximately 16% and 30%, respectively, are achieved in a general population of smokers.\textsuperscript{33}

Varenicline, a nicotinic receptor partial agonist, has demonstrated superior quit rates when compared with nicotine replacement and bupropion in several RCTs.\textsuperscript{30–32} The superior smoking cessation may result from better reductions in craving and withdrawal symptoms.\textsuperscript{40} Despite its greater cost, varenicline is cost-effective because of its improved quit rates.\textsuperscript{41} In 2009, the US Food and Drug Administration released a Public Health Advisory noting that both bupropion and varenicline have been associated with reports of changes in behavior such as hostility, agitation, depressed mood, and suicidal thoughts or actions. In patients with PAD specifically, comprehensive smoking cessation programs that included individualized counseling and pharmacological support significantly increased the rate of smoking cessation at 6 months compared with verbal advice to quit smoking (21.3% versus 6.8%, \(P = 0.02\)).\textsuperscript{29} Tobacco cessation interventions are particularly critical in individuals with thromboangiitis obliterans, because it is presumed that components of tobacco may be causative in the pathogenesis of this syndrome, and continued use is associated with a particularly adverse outcome.\textsuperscript{32}

\textbf{2.6.1.6. Recommendations for Antiplatelet and Antithrombotic Drugs.} Table 4 contains recommendations for antiplatelet and antithrombotic drugs. See Appendix 3 for supplemental information.

The writing group reviewed 5 RCTs and 1 meta-analysis related to antiplatelet therapy and PAD as part of this focused update.\textsuperscript{45–48,51} Although the 2002 Antithrombotic Trialists’ Collaboration meta-analysis demonstrated a significant reduction in cardiovascular events among symptomatic PAD patients randomized to antiplatelet therapy versus placebo, there was significant heterogeneity of enrollment criteria and antiplatelet dosing regimens among the trials.\textsuperscript{44} The results of 3 RCTs of aspirin use (100 mg daily) versus placebo for cardiovascular risk reduction among patients with PAD have been published since the 2005 guideline.\textsuperscript{45–47} These trials yielded mixed results, with the 2 larger trials with longer duration of follow-up demonstrating no benefit of aspirin.\textsuperscript{46,47} However, both of these studies enrolled only asymptomatic patients derived from population screening (not clinical populations) based on very mild decrements in ABI and thus represented relatively low-risk cohorts. The POPADAD (Prevention of Progression of Asymptomatic Diabetic Arterial Disease) study enrolled individuals with an ABI \(<0.99\), whereas the Aspirin for Asymptomatic Atherosclerosis trial used a cutpoint of ABI \(<0.95\) but calculated the ABI using the lower pedal pressure at the ankle. This method is in contrast to standard clinical practice (and this guideline) of using the higher pedal pressure at the ankle for determining ABI.\textsuperscript{46,37} These factors limit the generalizability of the results to patients with clinical PAD who are symptomatic and/or have lower ABI values and face a greater risk of ischemic events. The CLIPS (Critical Leg Ischemia Prevention Study) trial, which was the smallest of the 3 antiplatelet therapy trials reviewed, enrolled patients with more advanced PAD, defined by both symptoms and/or ABI values (ABI \(<0.85\)), and demonstrated a significant reduction

\textbf{Class I} & 1. Patients who are smokers or former smokers should be asked about status of tobacco use at every visit.\textsuperscript{25–28} (Level of Evidence: A) & New recommendation \\
& 2. Patients should be assisted with counseling and developing a plan for quitting that may include pharmacotherapy and/or referral to a smoking cessation program.\textsuperscript{36–39} (Level of Evidence: A) & New recommendation \\
& 3. Individuals with lower extremity PAD who smoke cigarettes or use other forms of tobacco should be advised by each of their clinicians to stop smoking and should be offered comprehensive smoking cessation interventions, including behavior modification therapy, nicotine replacement therapy, or bupropion. (Level of Evidence: B) & Modified recommendation (wording clarified and level of evidence changed from B to C). \\
& 4. In the absence of contraindication or other compelling clinical indication, 1 or more of the following pharmacological therapies should be offered: varenicline, bupropion, and nicotine replacement therapy.\textsuperscript{36–39} (Level of Evidence: A) & New recommendation \\
\hline
\end{tabular}
\caption{Recommendations for Smoking Cessation}
\end{table}

PAD indicates peripheral artery disease.
in cardiovascular ischemic events among subjects randomized to aspirin. Of note, this trial was stopped early because of poor recruitment, with only 366 of a planned 2000 patients enrolled. The 2009 meta-analysis of aspirin therapy for patients with PAD demonstrated a 34% risk reduction for nonfatal stroke among participants taking aspirin but no statistically significant reduction in overall cardiovascular events. This study included the CLIPS and POPADAD trials but not the Aspirin for Asymptomatic Atherosclerosis trial.

The recommended dose range of aspirin has been modified to 75 mg to 325 mg per day to reflect the doses studied in the aspirin clinical trials and in use in clinical practice. The 2005 recommendation of clopidogrel as an alternative to aspirin therapy is unchanged. Three clinical trials compared aspirin monotherapy therapy with clopidogrel as an alternative to aspirin therapy, with no new clinical trials having directly compared aspirin monotherapy therapy with clopidogrel.
since the CAPRIE (Clopidogrel versus Aspirin in Patients at Risk of Ischemic Events) study demonstrated an incremental benefit of clopidogrel.\textsuperscript{43} On the basis of the findings of the CHARISMA (Clopidogrel for High Atherothrombotic Risk and Ischemic Stabilization, Management, and Avoidance) trial, it may be reasonable to consider combination antiplatelet therapy with aspirin plus clopidogrel for certain high-risk patients who are not considered at increased risk of bleeding.\textsuperscript{48,49,52} Selection of an antiplatelet regimen for the PAD patient should be individualized on the basis of tolerance and other clinical characteristics (ie, bleeding risk) along with cost and guidance from regulatory agencies.

The WAVE (Warfarin Antiplatelet Vascular Evaluation) trial provided further evidence against the use of oral anticoagulation therapy in addition to antiplatelet therapy for prevention of cardiovascular events among patients with PAD, and the level of evidence is upgraded to B for this Class III recommendation.\textsuperscript{50}

The writing group emphasizes that selection of the optimal antiplatelet therapy and determination of optimum dosage in well-defined populations of patients with PAD are critical unanswered scientific questions. There is a need for additional data from large-scale RCTs and observational studies to investigate the efficacy and risk of antiplatelet medications across the spectrum of PAD defined according to symptom class (symptomatic versus asymptomatic) and objective measures of atherosclerosis severity (ie, ABI value).

To date, no clinical trials have examined the efficacy of new antithrombotic medications such as prasugrel, ticagrelor, or vorapaxar to reduce ischemic events in patients with lower extremity PAD.

### 2.6.3. Recommendations for Critical Limb Ischemia: Endovascular and Open Surgical Treatment for Limb Salvage

Table 5 contains recommendations for endovascular and open surgical treatment for limb salvage in patients with critical limb ischemia. See Appendix 3 for supplemental information.

The writing group has reviewed the results of the multicenter BASIL (Bypass Versus Angioplasty in Severe Ischaemia of the Leg) trial funded by the United Kingdom National Institute of Health Research and Health Technology Assessment Programme.\textsuperscript{54} During a 5-year period, 452 patients with severe limb ischemia (characterized by rest/night pain and tissue loss, such as skin ulceration and gangrene, and thus...
including patients defined by this PAD guideline syndrome term critical limb ischemia were randomly assigned to an initial treatment strategy of either open surgery or balloon angioplasty. Major clinical outcomes evaluated in this trial were amputation-free survival and overall survival. The initial results published in 2005 indicated that in patients with severe limb ischemia due to infragenual disease, the short-term clinical outcomes between bypass surgery–first and balloon angioplasty–first were similar. These initial results showed that bypass surgery–first was one third more expensive and was associated with higher morbidity than balloon angioplasty–first.

The trial also initially suggested that after 2 years, patients treated with balloon angioplasty–first had increased overall survival rates and fewer amputations. However, this early finding was based on a post hoc analysis of a relatively small number of outcome events. Thus, more prolonged follow-up was necessary to confirm or refute this finding. The results of a 2.5-year follow-up have been published and confirm that there was no significant difference in amputation-free survival and overall survival between the 2 treatment strategies. However, a bypass surgery–first approach was associated with a significant increase in overall survival of 7.3 months (95% CI: 1.2 to 13.4 months; \( P = 0.02 \)) and a trend toward improved amputation-free survival of 5.9 months (95% CI: 0.2 to 12.0 months; \( P = 0.06 \)) for those patients who survived for at least 2 years after randomization. In summary, for all patients in the trial, there was no significant difference between the 2 treatment strategies in amputation-free survival or overall survival. However, these data suggest that it is reasonable for a bypass surgery–first approach to be considered for these carefully selected patients to prolong amputation-free survival and overall survival. This study has also confirmed that the outcomes following prosthetic bypass were extremely poor. Balloon angioplasty, when possible, may be preferable to prosthetic bypass even in patients with a life expectancy of >2 years.

5. ANEURYSM OF THE ABDOMINAL AORTA, ITS BRANCH VESSELS, AND THE LOWER EXTREMITIES

5.2.8.1. Recommendations for Management Overview. Table 6 contains recommendations for management of abdominal aortic aneurysm (AAA). See Appendix 3 for supplemental information.

Although the methods of treatment for infrarenal abdominal aortic and iliac artery aneurysms have changed little over the past 5 years, a greater understanding of the appropriate application of these technologies and techniques has been gained. Overall, open and endovascular repair techniques have demonstrated clinical equivalence over time, with similar rates of overall and aneurysm-related mortality and morbidity.

For patients with an infrarenal AAA who are likely to live >2 years and who are good risk surgical candidates, open or endovascular intervention is indicated. There is no long-term advantage to either technique of aneurysm repair. This was clearly demonstrated in 2 large multicenter, randomized, prospective studies. The EVAR (United Kingdom Endovascular Aneurysm Repair) trial evaluated the outcomes of patients ≥60 years of age who were appropriate candidates for either endovascular or open repair of infrarenal AAAs that were at least 5.5 cm in diameter based on computed tomographic imaging. Over 5 years, 1252 patients were enrolled and randomly assigned to either stent graft or open aneurysm repair. The primary outcomes measures were all-cause mortality and aneurysm-related mortality, and data were analyzed on an intention-to-treat basis. Follow-up was a minimum of 5 years or until death, with a median postprocedural follow-up of 6 years. The treatment groups, which were 90.7% male with a mean age of 74 years, were uniform with regard to comorbidities. There was a significant difference in procedural mortality between endovascular and open repair (1.8% endovascular repair versus 4.3% open repair, \( P = 0.02 \), adjusted odds ratio: 0.39; 95% CI: 0.18 to 0.87). Over time, this initial benefit was not sustained. Over the period of observation, all-cause mortality in the endovascular group was 7.5 deaths per 100 person-years compared with 7.7 deaths per 100 person-years in the open-surgery group (\( P = 0.72 \); adjusted HR: 1.03; 95% CI: 0.86 to 1.23). Aneurysm-related mortality was also similar, with 1.0 death per 100 person-years in the stent graft group compared with 1.2 deaths per 100 person-years in the open-surgery group (\( P = 0.73 \); adjusted HR: 0.92; 95% CI: 0.57 to 1.49). Reintervention was required in 5.1% of patients treated with an endograft but in only 1.7% of those who underwent open surgery (\( P = 0.001 \)), underscoring the need for careful evaluation of the stent graft over time. These findings were consistent with those reported in another multicenter, randomized, prospective trial. The DREAM (Dutch Randomized Endovascular Aneurysm Repair) trial evaluated the long-term outcomes of patients with infrarenal aortic aneurysms ≥5 cm who were randomized to either endovascular or open surgical treatment. The primary outcome measure was all-cause mortality. There were no differences in demographic characteristics or comorbidities between the 178 patients assigned to open surgery and the 173 patients assigned to endovascular intervention. Similar
to the EVAR trial, the majority of patients in the DREAM trial were male (91.7%), with a mean age of 70 years. The minimum follow-up was 5 years, and the median was 6.4 years. Over this period of time the mortality rate of the 2 groups was not different. The overall survival rate was 69.9% in the open-surgery group and 68.9% among those undergoing stent graft repair (difference: 1.0%; 95% CI: 0.8 to 10.8; \( P = 0.97 \)). Although cardiovascular disease was the single most common cause of death, it accounted for only 33% of the deaths in the open-surgery group and 27.6% of the deaths in the endovascular treatment group. Deaths from noncardiovascular causes, such as cancer, were more common. During the follow-up period, freedom from secondary intervention was more common in the open-repair group compared with the endovascular treatment group (difference 11.5%; 95% CI: 2.0 to 21.0; \( P = 0.03 \)).

More recently, a third trial has buttressed the results of the EVAR and DREAM trials. The OVER (Open Surgery Versus Endovascular Repair Veterans Affairs Cooperative Study) trial randomized 881 veterans with AAA ≥5 cm or an associated iliac artery aneurysm ≥3 cm or an AAA ≥4.5 cm with rapid enlargement to surgical or endovascular repair.\(^6^\) The primary outcome was long-term, all-cause mortality. As with both the DREAM and EVAR trials, there were no differences in baseline demographic characteristics. The trial participants were overwhelmingly male (>99%), white (87%), and current or former smokers (95%). Over a mean follow-up of 1.8 years, there was no statistical difference in mortality, 7% versus 9.8% for endovascular and surgical repair, respectively (\( P = 0.13 \)). Interestingly, there were no differences in the rates of secondary therapeutic procedures or aneurysm-related hospitalizations between the groups, because increases...
in surgical complications offset the number of secondary endovascular repairs.

As with the EVAR trial, the DREAM and OVER trials confirmed that the early benefits of endovascular aneurysm repair, including a lower procedural mortality, are not sustained. Therefore, the method of aneurysm repair that is deemed to be most appropriate for each individual patient should be chosen. Endovascular treatment should not be used in patients who do not meet the established anatomical criteria or who cannot comply with the required follow-up imaging requirements. Patients require either computed tomography or magnetic resonance imaging of the engrafted segment of the aortoiliac segment at 1 month, 6 months, and then yearly to confirm that the graft has not moved and there are no endoleaks that have resulted in repressurization and/or growth of the aneurysm sac. If patients cannot be offered the indicated long-term follow-up evaluation and treatment because of the lack of access to required imaging modalities or inability to appropriately treat problematic endoleaks when identified, then endovascular repair should not be considered the optimal treatment method. Open surgical repair is indicated for those patients who do not meet the established criteria for endovascular treatment.

A patient whose general physical condition is deemed unsuitable for open aneurysm repair may not benefit from endovascular repair. This was suggested in a secondary protocol of the EVAR trial. The EVAR 2 trial randomized 404 patients with infrarenal aortic aneurysms of at least 5.5 cm in diameter who required open repair to receive either endovascular repair or no intervention. One hundred ninety-seven patients were randomized to the endovascular treatment group and 179 actually underwent stent graft placement. Of 207 patients randomly assigned to the no-treatment group, 70 had aneurysm repair. The primary outcome was death from any cause. The patients were followed up for a minimum of 5 years or until death. The median follow-up period was 3.1 years. Thirty-day operative mortality was 7.3%. Although a significant difference in aneurysm-related mortality between the 2 groups was identified (3.6 deaths per 100 person-years for endovascular therapy versus 7.3 deaths per 100 person-years without treatment, adjusted HR: 0.53; 95% CI: 0.32 to 0.89; \( P = 0.02 \)), this was not associated with longer survival. During follow-up there was no significant difference in overall mortality between the 2 groups (21.0 deaths per 100 person-years in the endovascular group versus 22.1 deaths per 100 person-years in the no-treatment group; HR for endovascular repair: 0.99; CI: 0.78 to 1.27; \( P = 0.97 \)). Although there was no observed benefit to the endovascular treatment of infrarenal AAAs in patients whose physical health was considered too poor to withstand open aneurysm repair in this trial, optimal management of this challenging patient population has not been definitively established. Additional studies are required to better define the role of endovascular aneurysm repair in patients with significantly impaired physical health who are considered to be at high surgical or anesthetic risk.

This table represents the relationships of writing group members with industry and other entities that were determined to be relevant to this document. These relationships were reviewed and updated in conjunction with all meetings and/or conference calls of the writing group during the document development process. The table does not necessarily reflect relationships with industry at the time of publication. A person is deemed to have a significant interest in a business if the interest represents ownership of ≥5% of the voting stock or share of the business entity, or ownership of ≥$10,000 of the fair market value of the business entity; or if funds received by the person from the business entity exceed 5% of the person's gross income for the previous year. Relationships that exist with no financial benefit are also included for the purpose of transparency. Relationships in this table are modest unless otherwise noted.

According to the ACCF/AHA, a person has a relevant relationship if: (a) The relationship or interest relates to the same or similar subject matter, intellectual property or asset, topic, or issue addressed in the document; or (b) the company/entity (with whom the relationship exists) makes a drug, drug class, or device addressed in the document, or makes a competing drug or device addressed in the document; or (c) the person or a member of the person's household, has a reasonable potential for financial, professional or other personal gain or loss as a result of the issues/content addressed in the document.

*Writing group members are required to recuse themselves from voting on sections to which their specific relationships with industry and other entities may apply.
†Indicates significant relationship.
‡No financial benefit.
DSMB indicates Data and Safety Monitoring Board; NHLBI, National Heart, Lung, and Blood Institute; NIH, National Institutes of Health; and PI, principal investigator.

This table represents the relationships of reviewers with industry and other entities that were disclosed at the time of peer review and determined to be relevant. It does not necessarily reflect relationships with industry at the time of publication. A person is deemed to have a significant interest in a business if the interest represents ownership of ≥5% of the voting stock or share of the business entity, or ownership of ≥$10 000 of the fair market value of the business entity; or if funds received by the person from the business entity exceed 5% of the person's gross income for the previous year. A relationship is considered to be modest if it is less than significant under the preceding definition. Relationships that exist with no financial benefit are also included for the purpose of transparency. Relationships in this table are modest unless otherwise noted. Names are listed in alphabetical order within each category of review.

According to the ACCF/AHA, a person has a relevant relationship if: (a) The relationship or interest relates to the same or similar subject matter, intellectual property or asset, topic, or issue addressed in the document; or (b) the company/entity (with whom the relationship exists) makes a drug, drug class, or device addressed in the document, or makes a competing drug or device addressed in the document; or (c) the person or a member of the person’s household, has a reasonable potential for financial, professional or other personal gain or loss as a result of the issues/content addressed in the document.

*Significant relationship.
†No financial benefit.

ACCF indicates American College of Cardiology Foundation; AHA, American Heart Association; PAD, peripheral artery disease; PVD, peripheral vascular disease; SCAI, Society for Cardiovascular Angiography and Interventions; SIR, Society of Interventional Radiology; SVM, Society for Vascular Medicine; and SVS, Society for Vascular Surgery.

</table>

### Long-term (5 to 9 y) all-cause mortality

- 1\textsuperscript{st} outcomes included: 1) procedure failure, 2) short-term major morbidity, 3) in-hospital and ICUs associated with initial repair, 4) other procedure-related morbidities such as incisional hernia or new or worsened claudication, 5) HRQOL, and 6) erectile dysfunction. 2\textsuperscript{nd} outcomes cover short-term perioperative period
- Perioperative mortality (9.4 or inpatient) was lower for endovascular repair (0.5% vs 3.0%; \(P=0.004\)); no significant difference in mortality at 2 y (7.0% vs 9.8%; \(P=0.13\)). Patients in endovascular repair group had reduced median procedure time (2.9 vs 3.7 h), blood loss (200 vs 1000 mL), transfusion requirement (0 vs 1.0 units), duration of mechanical ventilation (3.6 vs 5.0 h), hospital stay (3 vs 7 d), and ICU stay (1 vs 4 d), but required substantial exposure to fluoroscopy and contrast. No differences between the 2 groups in major morbidity, procedure failure, 2\textsuperscript{nd} therapeutic procedures, aneurysm-related hospitalizations, HRQOL, or erectile function.
- 10-y CV mortality: Men: HR: 4.2; 95% CI: 3.3 to 5.4; Women: HR: 3.5; 95% CI: 2.4 to 5.1
- Measurement of ABI may improve accuracy of CV risk prediction beyond FRS.

### CV events (nonfatal MI, nonfatal stroke, and CV death)

- 1\textsuperscript{st} outcomes included: 1) procedure failure, 2) short-term major morbidity, 3) in-hospital and ICUs associated with initial repair, 4) other procedure-related morbidities such as incisional hernia or new or worsened claudication, 5) HRQOL, and 6) erectile dysfunction. 2\textsuperscript{nd} outcomes cover short-term perioperative period
- All-cause mortality, major bleeding, and individual
- 5000 patient meta-analysis with \(-88\%\) power to detect a 2% difference (from 10% to 7.5%) and 70% power to detect a 20% difference (from 10% to 20%).
- Effect of any ASA on prevention of composite CV endpoints, \(P=0.13\).
- Effect of any ASA on prevention of composite CV endpoints: RR: 0.88; 95% CI: 0.76 to 1.04
- In patients with PAD, treatment with ASA alone or with dipyridamole resulted in

(Continued)
### Prevention of progression of arterial disease and diabetes (POPADAD) trial: factorial randomized placebo-controlled trial of aspirin and antioxidants in patients with diabetes and asymptomatic PAD

- **Study Title**: Prevention of progression of arterial disease and diabetes (POPADAD) trial: factorial randomized placebo-controlled trial of aspirin and antioxidants in patients with diabetes and asymptomatic PAD
- **Aim of Study**: To determine whether ASA and antioxidant therapy, combined or alone, are more effective than placebo in reducing development of CV events in patients with diabetes mellitus and asymptomatic PAD
- **Study Type**: Multicenter, randomized, double-blind, 2 × 2 factorial, placebo-controlled trial
- **Study Size**: 1276 Adults of either sex, >40 y old, with type 1 or type 2 diabetes who were determined to have asymptomatic PAD as detected by lower-than-normal ABI (≤0.99). The trial used a higher cut-off point (0.99 vs 0.9) because it is recognized that calcification in the vessels of people with diabetes can produce a normal or high ABI, even in the presence of arterial disease.
- **Inclusion Criteria**: People with evidence of symptomatic CV disease; those who use ASA or antioxidant therapy on a regular basis; those with peptic ulceration, severe dyspepsia, a bleeding disorder, or intolerance to ASA; those with suspected serious physical illness (such as cancer), which might...
Composite of initial fatal or nonfatal coronary event or stroke or revascularization

1 endpoint event: 13.5 per 1000 person-years; 95% CI: 12.2 to 15.0. No statistically significant difference was found between groups (13.7 events per 1000 person-years in the ASA group vs 13.3 in the placebo group; HR: 1.03, 95% CI: 0.94 to 1.04). 2 endpoint (vascular event): 22.8 per 1000 person-years; 95% CI: 21.0 to 24.8, and no statistically significant difference was found between groups (22.8 events per 1000 person-years in the ASA group vs 22.9 in the placebo group; HR: 1.00, 95% CI: 0.85 to 1.17). No significant difference in all-cause mortality between groups, 176 vs 186 deaths, respectively; HR: 0.95, 95% CI: 0.77 to 1.16. An initial event of major hemorrhage requiring admission to hospital occurred in 34 participants (2.5 per 1000 person-years) in the ASA group and 20 (1.5 per 1000 person-years) in the placebo group (HR: 1.71, 95% CI: 0.99 to 2.97).

2 hierarchical composite 1 endpoints of death from CAD or stroke, nonfatal MI or stroke, or amputation above the ankle with CLI; and death from CAD or stroke

Overall, 116 of 638 1 events occurred in the ASA groups compared with 117 of 638 in the no-ASA groups (18.2% vs 18.3%). 43 deaths from CAD or stroke in the ASA groups compared with 35 in the no-ASA groups (6.7% vs 5.5%). Among the antioxidant groups, 117 of 640 (18.3%) 1 events occurred compared with 116 of 636 (18.2%) in the no-antioxidant groups. There were 42

Comparison of ASA and no-ASA groups—Composite endpoint: P=0.86
Death from CAD or stroke: P=0.36
Comparison of antioxidant and no-antioxidant groups—Composite endpoint: P=0.085

ASA groups 1 events: HR: 0.98, 95% CI: 0.73 to 1.26 ASA groups; deaths from CAD or stroke: HR: 1.23 (0.79 to 1.93) Antioxidant groups; 1 events: HR: 1.03, 95% CI: 0.79 to 1.33 Antioxidant groups deaths from CAD or stroke: HR: 1.21, 95% CI: 0.78 to 1.89

This trial does not provide evidence to support the use of ASA or antioxidants in primary prevention of CV events and mortality in the population with diabetes studied.

Trial Conclusion (as Reported in Study Article)

A statistically nonsignificant decrease in the 1 endpoint of CV events and a significant reduction in nonfatal stroke: Results for the 1 endpoint may reflect limited statistical power. Additional RCTs are needed to establish a net benefit and bleeding risks in PAD.

Other Information

Nonfatal MI, nonfatal stroke, and CV death in the population of patients who received any ASA therapy, with or without dipyridamole: 2 outcomes were all-cause mortality with or without a fatal CV event. Results are for the 1 endpoint. The 1 safety outcome evaluated occurrence of major bleeding as defined by each study. ITT analysis used.

### Study Title: Mortality and vascular morbidity in older adults with asymptomatic vs symptomatic PAD (getABI)\(^{11}\)

**Aim of Study:** To assess risk of mortality and vascular morbidity in elderly persons with asymptomatic vs symptomatic PAD in the primary care setting.

**Study Type:** Prospective cohort study.

**Study Size:** 6880 representative unselected patients 65 y of age: 5392 patients had no PAD, 836 had asymptomatic PAD (ABI: 0.9 without symptoms), and 593 had symptomatic PAD (lower extremity peripheral revascularization, amputation as a result of PAD, or intermittent claudication symptoms regardless of ABI).

- **Inclusion:** Age 65 y, legally competent, and able to cooperate appropriately and provide written informed consent\(^{64}\).
- **Exclusion:** Life expectancy of 6 mo as judged by the general practitioner\(^{64}\).

### Study Title: Effectiveness of a smoking cessation program for PAD patients\(^{65}\)

**Aim of Study:** To test the effectiveness of a smoking cessation program designed for patients with PAD.

**Study Type:** RCT

**Study Size:** 124

- **Inclusion:** Diagnosis of lower extremity PAD, defined as at least 1 of the following: ABI <0.90 in at least 1 lower extremity; toe brachial index <0.60; objective evidence of arterial occlusive disease in 1 lower extremity by duplex ultrasound, MRA, or CTA; prior leg arterial revascularization or amputation due to PAD, and current smoking (defined as smoking at least 1 cigarette/d, at least 6 d/wk). Additional inclusion criteria: desire to quit smoking in the next 30 d, age >18 y, ability to speak and write English, no participation in a smoking cessation program in the past 30 d, and consumption of <21 alcoholic drinks per wk.
- **Exclusion:** N/A
method assessed by 1-y survival graft patency, and events Major adverse CV 16-mo follow-ups (as Reported in Study Article) at the 3- and puff, in the past 7 a cigarette, even a ‘Have you smoked smoking (ie, point prevalence of Tobacco use 7-d during follow-up. because of PAD or amputation revascularization peripheral including stroke or carotid revascularization, and lower extremity peripheral vascular, including peripheral revascularization or amputation because of PAD during follow-up.

<tbody>
<tr>
<td>The combination of an oral anticoagulant and antiplatelet therapy was no more effective than antiplatelet therapy alone in preventing major CV complications and was associated with an increase in life-threatening bleeding.</td>
<td>Safety outcomes were life-threatening, moderate, or minor bleeding episodes.</td>
</tr>

<tr>
<td>First coprimary outcome: MI, stroke, or death from CV causes</td>
<td>MI, stroke, or death from CV causes occurred in 132 of 1080 patients receiving combination therapy (12.2%) and in 144 of 1081 patients receiving antiplatelet therapy alone (13.3%). MI, stroke, severe ischemia, or death from CV causes occurred in 172 patients receiving combination therapy (15.9%) compared with 188 patients receiving antiplatelet therapy alone (17.4%). Life-threatening bleeding occurred in 43 patients receiving combination therapy (4.0%) compared with 13 patients receiving antiplatelet therapy alone (1.2%).</td>
<td>MI, stroke, or death from CV causes: RR: 0.92; 95% CI: 0.73 to 1.16 MI, stroke, severe ischemia, or death from CV causes: RR: 0.91; 95% CI: 0.74 to 1.12 Life-threatening bleeding: RR: 3.41; 95% CI: 1.84 to 6.35</td>
